TDDE07 Bayesian Learning - Lab 4

Erik Linder-Norén - erino397

16 Maj, 2017

1. Poisson regression - the MCMC way.

(a)

In Figure 1 I have plotted the normal approximation of β_{MLE} with uncertainty. The β_{MLE} can be seen in Table 1. Significant covariates are MinBidShare, Sealed, VerifyID and MajBlem.

	Const	PowerSeller	VerifyID	Sealed	Minblem	MajBlem	LargNeg	LogBook	MinBidShare
1	1.072	-0.021	-0.395	0.444	-0.052	-0.221	0.071	-0.121	-1.894

Table 1: MLE of beta by glm model fitting

(b)

By numerical optimization I determined the β_{MLE} coefficients to be the values seen in Figure 2. They closely resemble the values in the GLM model in (a). My implementation of the log of the poisson model with a normal prior can be found in Appendix A.

	Const	PowerSeller	VerifyID	Sealed	Minblem	MajBlem	LargNeg	LogBook	MinBidShare
1	1.070	-0.021	-0.393	0.444	-0.052	-0.221	0.071	-0.120	-1.892

Table 2: MLE of beta by numerical optimization (normal approximation)

(c)

After having implemented the Metropolis Hastings simulation method and simulated 20000 draws from the posterior distribution from (b) I set the β values as the mean of the draws, while ommitting the first 10% of the draws because of the burn-in. These values can be seen in Table 3.

	Const	PowerSeller	VerifyID	Sealed	Minblem	MajBlem	LargNeg	LogBook	MinBidShare
1	1.070	-0.020	-0.394	0.441	-0.057	-0.223	0.069	-0.118	-1.892

Table 3: Mean values of betas drawn during Metropolis Hastings simulation

The convergergence of the parameters can be seen in Figure 1, where I have taken the mean value of every sequental beta drawn from the posterior and plotted it to visualize the auto-correlation between draws, and to see how the beta drawn asymptotically approaches somewhat stationary values. My implementation of the Metropolis Hastings algorithm can be found in Appendix A.

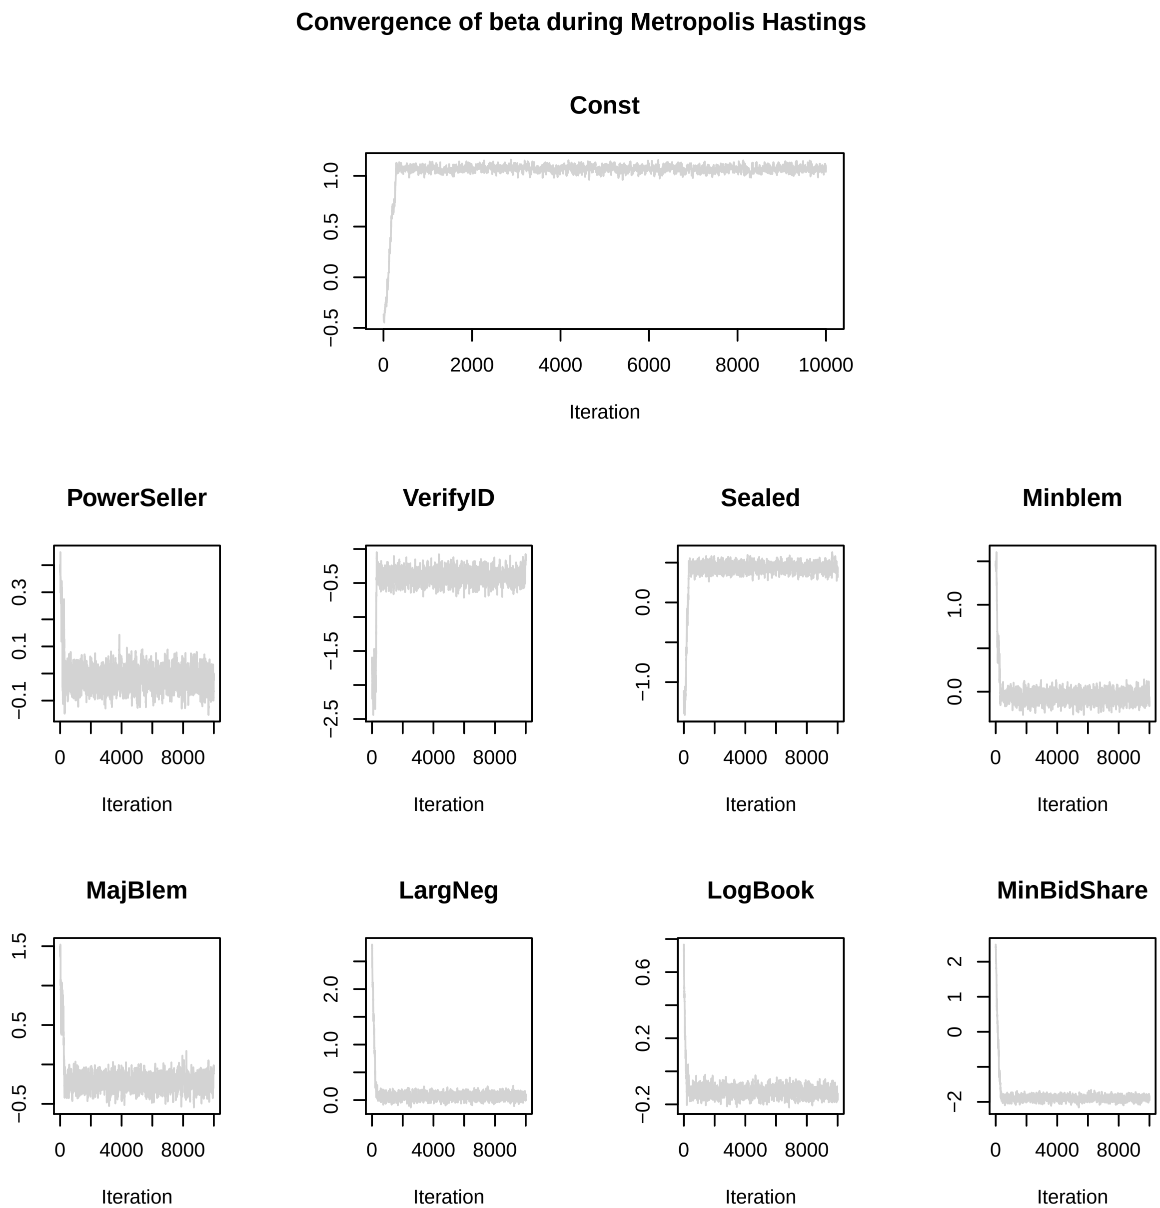

Figure 1: Convergence of betas drawn during Metropolis Hastings simulation

(d)

After having determined the predictive distribution of the sample $\hat{y}$ as $p(\hat{y}|\lambda) \sim Poisson(\lambda)$, where $\lambda = e^{\hat{X}\beta}$ using the betas draws during the simulation in (c), I got the distribution seen in Figure 2. The probability that the sample has zero bidders by this distribution was $p(0|\lambda) \approx 0.36$.

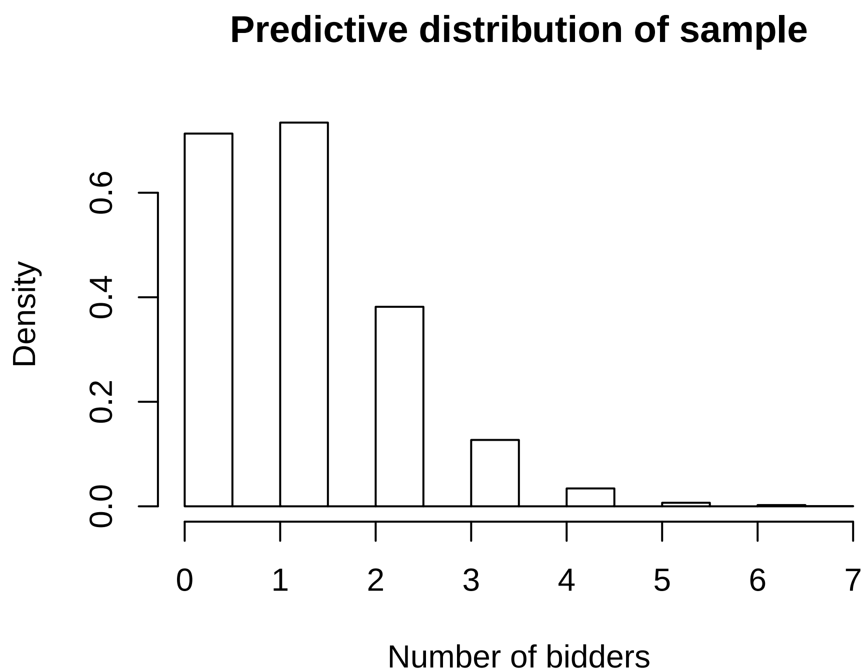

Figure 2: Predictive distribution of sample

Appendix A
